

Sokketsu

Stop agent payments with typed decisions, not generated text.

Live on Solana devnet · Alpenglow · finalized in 858 ms

PROBLEM

AI agents are starting to pay for work. But an LLM answers in prose.

ASK AN LLM: "RELEASE THE ESCROW?"

"I reviewed this request. The report appears to have been delivered and the payer seems to have approved it. That said, the scope of the approval is not fully clear… releasing the funds is probably fine, but to be safe…"

WHY IT FAILS

- A program can't act on "probably fine".
- Nobody can check who decided, or how sure.
- Waiting ~12.8 s for finality breaks the flow.

SOLUTION

A typed decision the chain can verify — and settle in under a second.

01 · TYPED

Jev returns only a choice and a probability

```
decision:    "release"
probability: 97%
```

02 · SIGNED

Our oracle signs it; the program checks Ed25519 on-chain

Tampered, re-used or unsigned decisions are rejected.

03 · SETTLED

Funds move only on a signed release ≥ 70%

Measured on Alpenglow devnet: 858 ms to finalized.

HOW IT WORKS

Two clicks. One wallet approval.

01
Deposit
payer → vault PDA

→

02
Jev decides
choice + probability

→

03
Verify
Ed25519 · on-chain

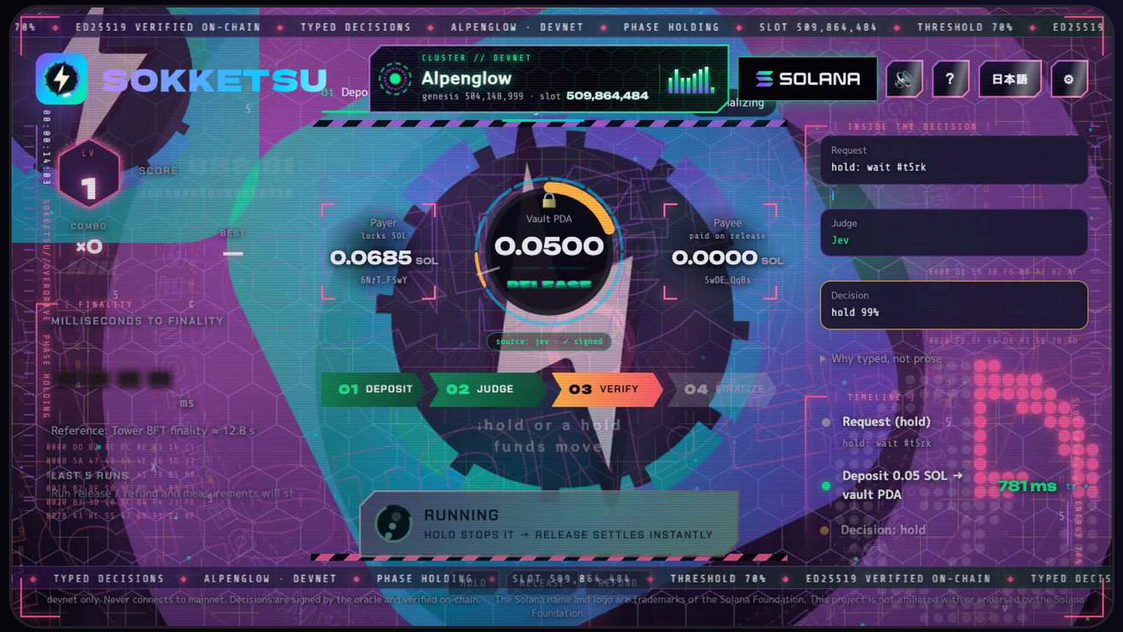

→

04
Finalize
Alpenglow

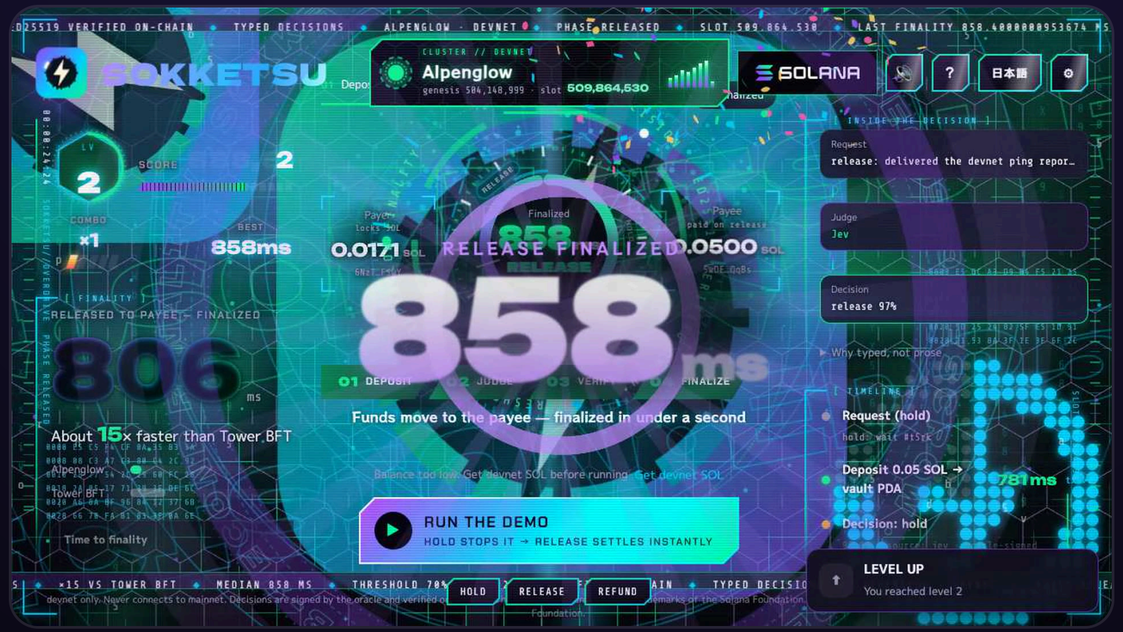

- The wallet signs only the deposit. Settlement is sent by an in-page operator key.
- hold stops the payment — not a single lamport moves. release pays the payee.
- No wallet? "Try it" creates a throwaway devnet key and funds it from our faucet.

LIVE DEMO · DEVNET

Stopped, then settled — on the live site.

hold 99% — the vault locks, the payee gets nothing.

release 97% — finalized in 858 ms.

MEASURED ON ALPENGLOW DEVNET

858 ms

send → finalized · about 15× faster than Tower BFT (~12.8 s)

`0 ms sent → 451 ms processed → 858 ms finalized`

`slot 509,864,530 · tx 4ondkUqtcL…bF4v8a · measured with WebSocket signatureSubscribe (processed / finalized)`

WHY SOLANA

Agent payments need a chain that settles as fast as the agent decides.

01 · ALPENGLOW

Sub-second finality

The decision and the payment settle together. 858 ms measured.

02 · ED25519

Native signature verification

The program reads the Ed25519 instruction to trust a signed judgment cheaply.

03 · FEES

A fraction of a cent

5,000 lamports per signature — cheap enough for every agent payment.

TRUST MODEL

Who can settle — enforced by the program.

CASE	RULE	ERROR
Decision from Jev	Anyone may submit it — the payer can't block a valid release	—
Mock decision (fallback)	Only the payer or its registered operator key	`UnauthorizedSubmitter`
No / altered / re-used signature, or changed source	Rejected before any lamport moves	`MissingOracleSignature` · `BadOracleSignature`
Refund / close	Anyone may send; funds always return to the payer	`RefundNotAllowed` · `NotFinished`

GO-TO-MARKET (PLAN)

Start where agents already pay for tasks.

WHO

Agent marketplaces & task platforms

Teams that escrow payment for work done by AI agents and need a release rule they can audit.

HOW

Open-source program + API

Deploy the Anchor program, call `/api/judge` for a signed decision, settle in one transaction.

NEXT

From devnet to production

Verify the model provider's own signature on-chain, freeze the program, then audit before mainnet.
